Application

A sensor set is used together with an electronic heat meter for measuring flow and return flow temperatures in heating installations.

Depending on the type, the sensors can be used directly in the liquid flow (direct sensor) or fitted in a sensor pocket.

The sensor has a built-in platinum resistor with an electric resistance, which changes with the temperature. Measuring the resistance value gives an analog indication of the temperature.

A heat meter calculates the differential temperature of a heating installation on the basis of measured flow and return flow temperatures. Based on the differential temperature and the volume of liquid measured, the energy consumed can then be calculated and summed up.
